

ARDUINO: SPI COMMUNICATION & SD CARD MODULE

Let's Explore How Arduino Talks to Devices!

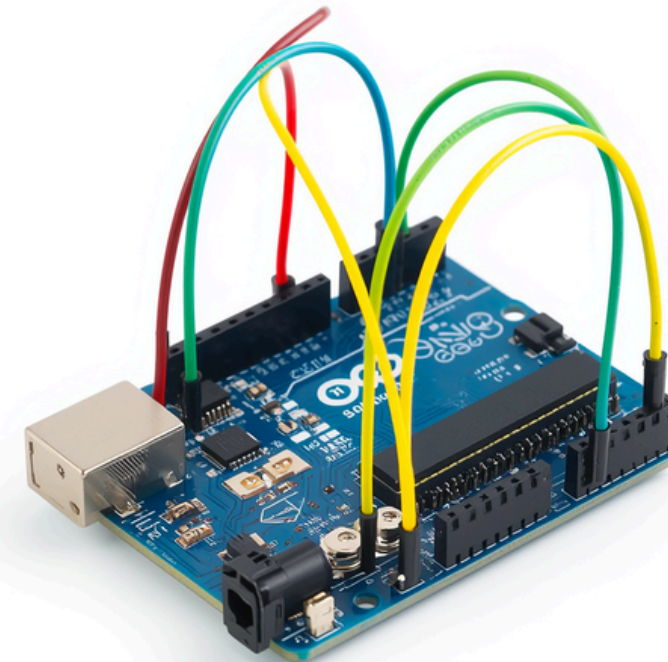

What is Arduino?

Arduino is a tiny computer that can control electronics! Think of it as a brain for your projects.

Arduino helps us create cool electronics projects!

It can talk to many devices like sensors, lights, and memory cards.

With Arduino, you can make robots, games, and so much more!

Why Do Devices Need to Talk?

Think of it like friends sharing secrets with walkie-talkies! Arduino needs to talk to other devices like sensors, screens, and memory cards to work together.

When you want to check the temperature, Arduino asks a sensor. When you want to save data, Arduino talks to an SD card. Without communication, devices can't help each other!

Just like you chat with friends to share ideas, Arduino chats with devices to create amazing projects!

Meet SPI: The Secret Language

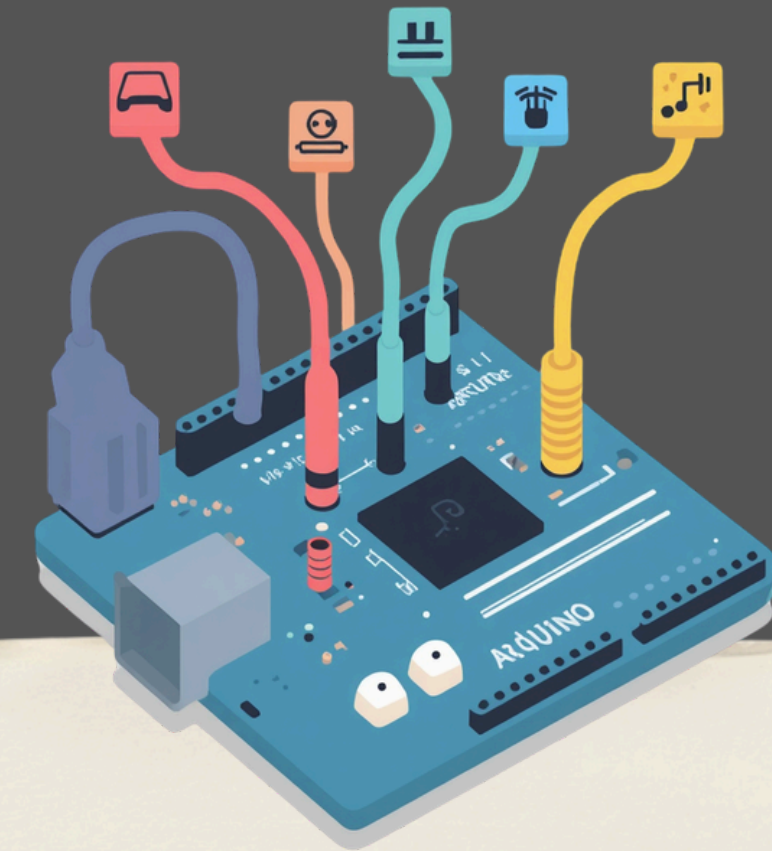

What is SPI?

SPI is a special way Arduino talks quickly and clearly to other devices like SD cards and sensors!

Think of it like a super-fast walkie-talkie system where Arduino can send and receive messages at the same time.

The 4 Magic Wires of SPI:

- MOSI (Master Out, Slave In) – Arduino TALKS and sends data
- MISO (Master In, Slave Out) – Arduino LISTENS and receives data
- SCK (Clock) – Keeps perfect TIME so messages don't get mixed up
- SS (Slave Select) – CHOOSES which device to talk to

How SPI Works - The Conversation

Arduino Sends Data (MOSI) → Arduino talks to the device, sending information through the MOSI wire.

Arduino Listens (MISO) → The device replies back, and Arduino listens through the MISO wire.

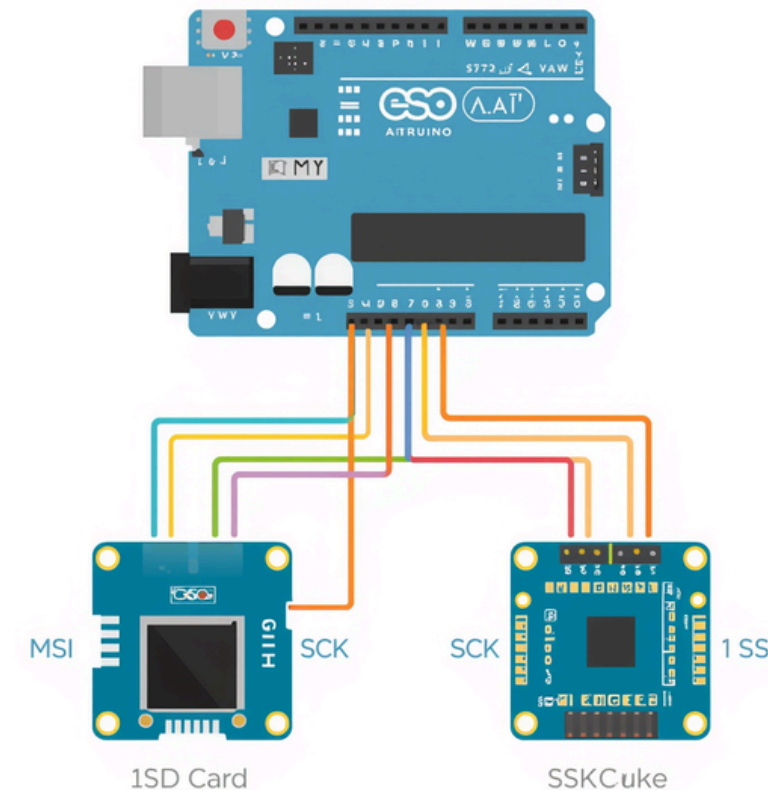

Clock Keeps Time (SCK) → The clock wire beats like a drum, keeping both in sync so messages don't get mixed up!

It's like a perfectly timed conversation between friends!

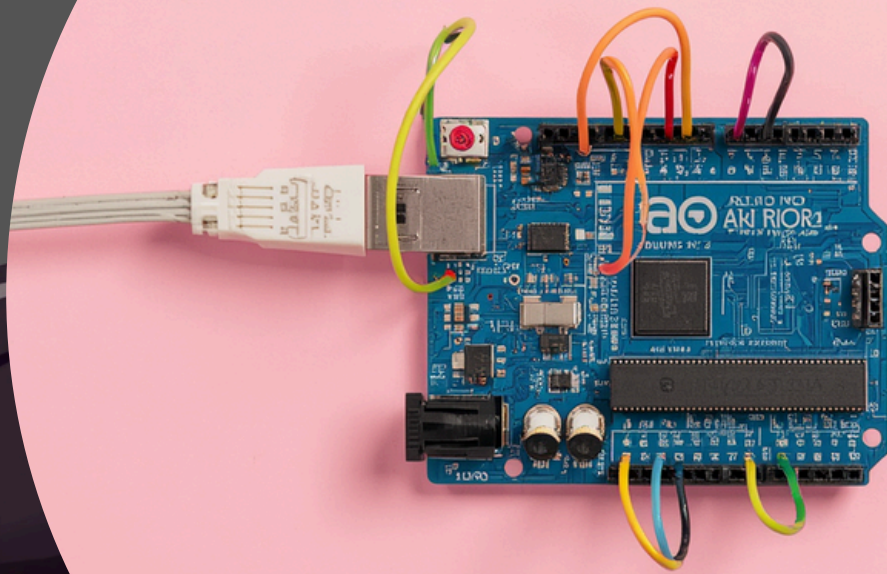

Connecting SPI Devices

Multiple devices can share the same SPI bus! Each device connects to MOSI, MISO, and SCK wires. But here's the trick: each device gets its own SS (Slave Select) pin. When Arduino wants to talk to a specific device, it activates that device's SS pin. This way, devices take turns talking without confusion!

What is an SD Card Module?

SD cards are amazing little storage devices! They can hold lots of information like photos, music, and data from your Arduino projects.

When we connect an SD card module to Arduino, we can save sensor readings, create data logs, or store messages!

Fun Fact: These tiny cards can hold thousands of pictures! That's like having a huge digital notebook in something smaller than your thumb!

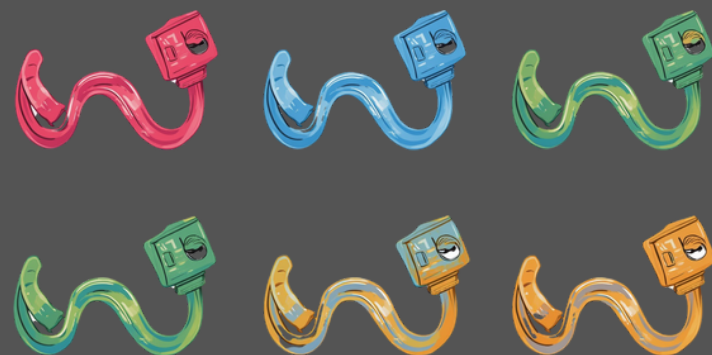

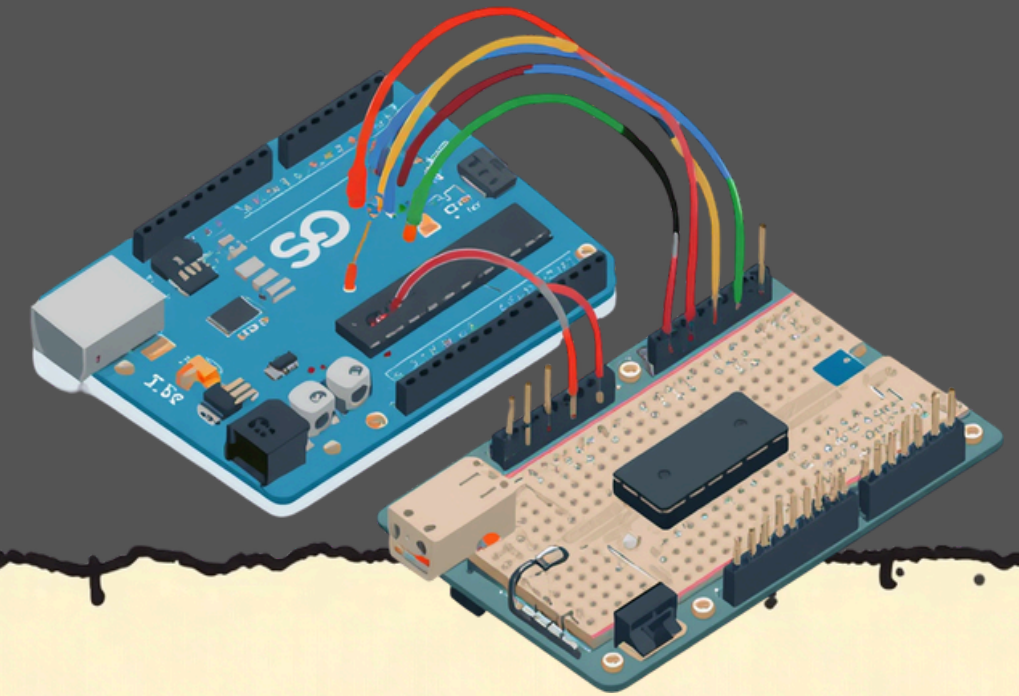

Wiring the SD Card Module

Connect these wires from Arduino to SD Card Module:

- MOSI → Pin 11 (Arduino sends data)
- MISO → Pin 12 (Arduino receives data)
- SCK → Pin 13 (Clock signal)
- CS/SS → Pin 10 (Select the SD card)
- VCC → 5V (Power)
- GND → GND (Ground)

Pro Tip: Use matching colored wires for each connection! This makes it easier to check your work and find mistakes. The colors we learned for SPI lines will help you remember which wire goes where!

Let's See Some Code!

```
#include <SPI.h>
#include <SD.h>
void setup() {
  SD.begin(10); // Start SD card
  File myFile = SD.open("hello.txt", FILE_WRITE);
  myFile.println("Hello World!");
  myFile.close();
}
```

💡 SPI.h lets Arduino talk fast!

💡 SD.h helps read/write files!

💡 We write "Hello World!" to our SD card!

How Does the Code Work?

Start SPI Communication

Arduino wakes up and says "Hello!" to the SD card module using the SPI language. This gets everything ready to talk!

Open File on SD Card

Arduino finds and opens the file you want, like opening a notebook to write in.

Write or Read Data

Now Arduino can save information or read what's already there!

Real-World Projects Using SD Cards

106

Here are exciting projects you can build with Arduino and SD cards!

Data Logger – Record weather data like temperature and humidity over time

Music Player – Store and play your favorite songs from the SD card

Game Score Keeper – Save your high scores so you never lose them

Camera Module – Capture photos and store them on your SD card

Why Learn SPI & SD Cards?

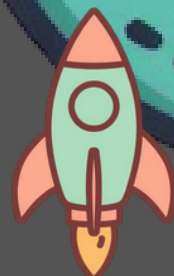

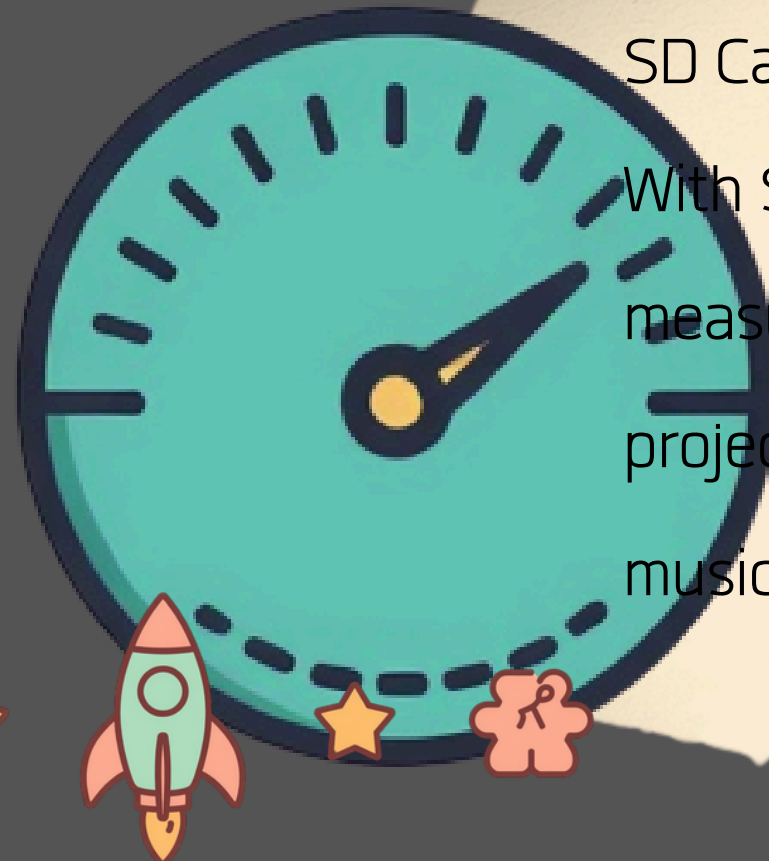

SPI is Super Fast & Powerful!

SPI communication lets Arduino talk to devices really quickly – much faster than other methods! This means your projects can respond instantly and handle lots of data without slowing down. Learning SPI opens doors to connecting many cool devices like sensors, displays, and memory cards all at once!

SD Cards Store Tons of Information!

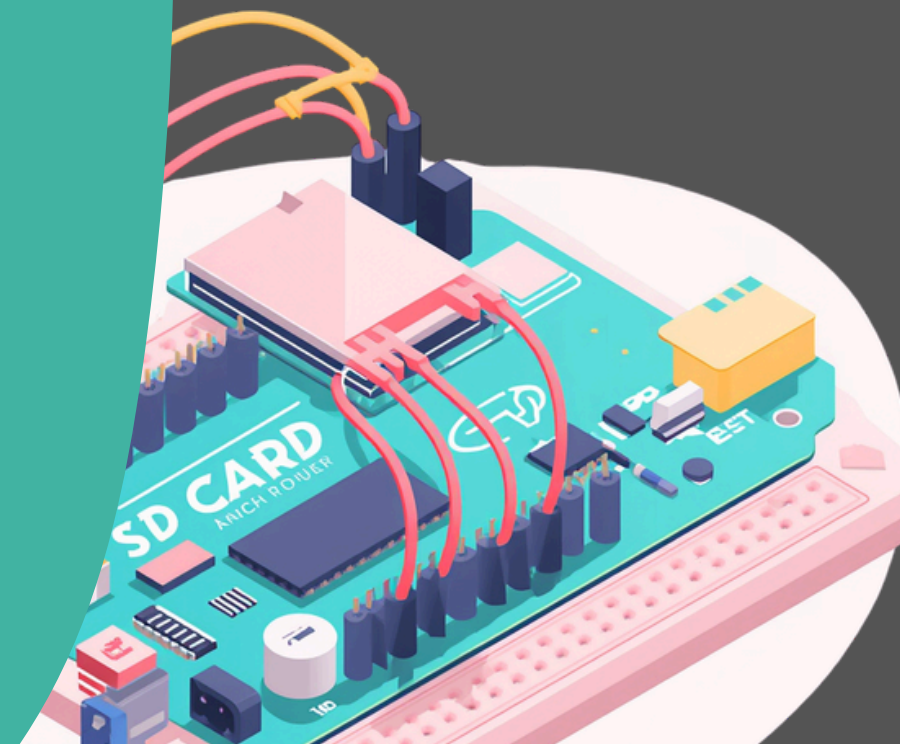

With SD card modules, your Arduino can save thousands of measurements, songs, or game scores! This helps you build exciting projects like weather stations that remember data for months, or music players with your favorite songs. The possibilities are endless!

Quick Recap

Arduino talks to devices using SPI communication. SPI uses four special wires: MOSI (sends data), MISO (receives data), SCK (keeps time), and SS (selects which device to talk to). These wires work together like a team!

SD card modules store data for your Arduino projects – like a tiny memory box! With simple code, Arduino can read and write information to the SD card. Now you know the basics of SPI and SD card

Fun Quiz Time!

An illustration of three children, two girls and one boy, sitting at a table and working on a project. The girl on the left is smiling and looking towards the center. The girl in the middle is smiling and looking down at the project. The boy on the right is partially visible, also looking at the project. They are all wearing casual clothing. A speech bubble with the text "Let's Build Together!" is positioned on the right side of the image.

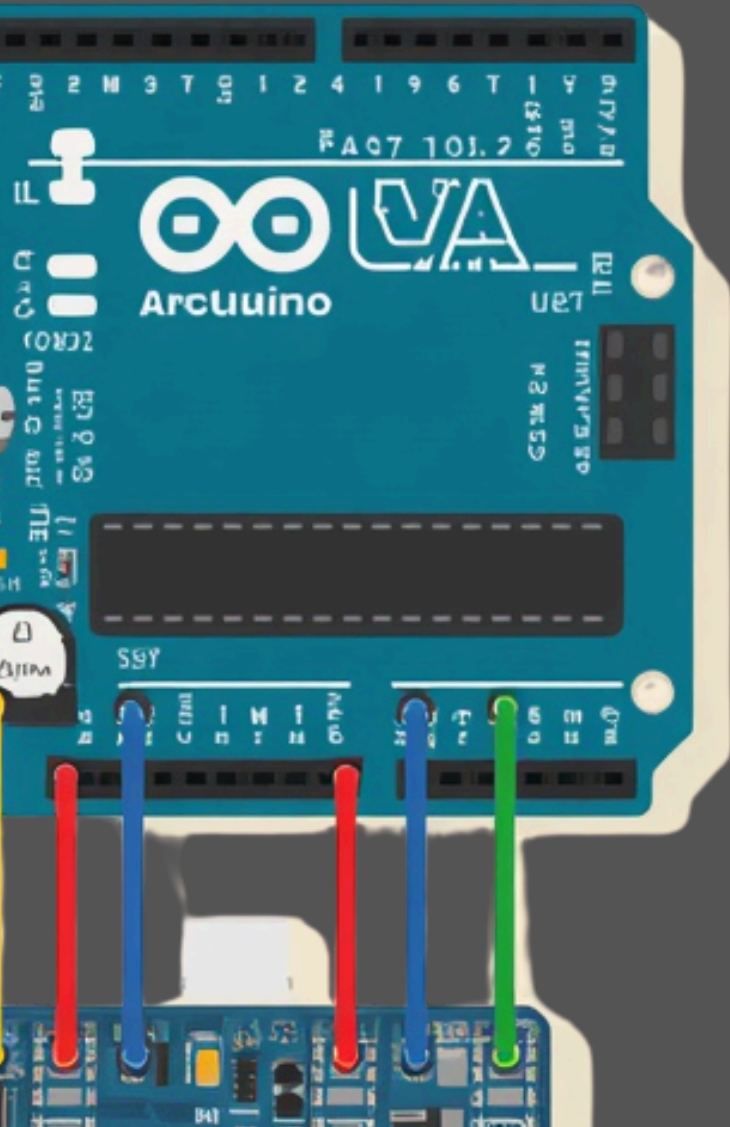

Let's Build Together!

Now it's your turn to explore! Try connecting an SD card module to your Arduino and see what you can create.

Simple Project Ideas:

- Build a temperature logger that saves readings
- Create a digital diary that stores your notes
- Make a quiz game that keeps high scores

Remember: You can create amazing things!

Thank you!
